(57) **ABSTRACT**

The invention relates to improved methods of producing and recovering *B. anthracis* protective antigen (PA), especially modified PA which is protease resistant, and to methods of using of these PAs or nucleic acids encoding these PAs for eliciting an immunogenic response in humans, including responses which provide protection against, or reduce the severity of, *B. anthracis* bacterial infections and which are useful to prevent and/or treat illnesses caused by *B. anthracis*, such as inhalation anthrax, cutaneous anthrax and gastrointestinal anthrax.

METHODS OF USING *BACILLUS ANTHRACIS* PROTECTIVE ANTIGEN SEQUENCES FOR VACCINATION

CROSS-REFERNCE TO RELATED APPLICATIONS

This is a divisional application of U.S. patent application Ser. No. 12/816,285, filed Jun. 15, 2010, now U.S. Pat. No. 8,044,189, which is a divisional application of U.S. patent application Ser. No. 10/290,712, filed Nov. 8, 2002, now U.S. Pat. No. 7,763,451, which claims the benefit of U.S. Provisional Application No. 60/344,505 filed Nov. 9, 2001.

FIELD OF THE INVENTION

This invention relates to improved methods of preparing *Bacillus anthracis* protective antigen (PA) for use in vaccines.

BACKGROUND

Anthrax, a potentially fatal disease, is caused by *Bacillus anthracis*. The virulence of this pathogen is mediated by a capsule of a poly-D-γ-glutamic acid and an exotoxin composed of three proteins (14, 16, 17). The three protein components are the protective antigen (PA, 82 KDa), lethal factor (LF, 90.2 KDa) and edema factor (EF, 88.8 KDa) These proteins, non-toxic by themselves, form lethal toxins when combined with an activated PA (16). The genes coding for these three protein components and the capsule are found in the endogenous plasmids pXO1 and pXO2, respectively (29).

The capsule of *Bacillus anthracis*, composed of poly-D-glutamic acid, serves as one of the principal virulence factors during anthrax infection. By virtue of its negative charge, the capsule is purported to inhibit host defense through inhibition of phagocytosis of the vegetative cells by macrophages. In conjunction with lethal factor (LF) and edema factor (EF), whose target cells include macrophages and neutrophils, respectively, the capsule allows virulent anthrax bacilli to grow virtually unimpeded in the infected host. Spores germinating in the presence of serum and elevated CO_2 release capsule through openings on the spore surface in the form of blebs which may coalesce before sloughing of the exosporium and outgrowth of the fully encapsulated vegetative cell. It has not been established that spore encapsulation plays a role in the early events of anthrax infection. The capsule appears exterior to the S-layer of the vegetative cell and does not require the S-layer for its attachment to the cell surface.

There is only indirect evidence, albeit extensive, identifying the components of vaccine-induced immunity to anthrax and there is evidence that anti-PA neutralizing antibody titers can be a reliable surrogate marker for protective immunity (23). The protective antigen (PA), seems to be an essential component of all vaccines for anthrax (7, 18, 30): both mono and polyclonal antibodies to PA neutralize the anthrax toxin and confer immunity to *B. anthracis* in animal models. The US licensed vaccine for anthrax "Anthrax Vaccine Adsorbed" (AVA) is produced from the formalin-treated culture supernatant of *B. anthracis* Sterne strain, V770-NP1-R ($pXO1^+$, $pXO2^-$), adsorbed onto aluminum hydroxide (22). Although AVA has been shown to be effective against cutaneous infection in animals and humans and against inhalation anthrax by rhesus monkeys (12), it has several limitations: 1) AVA elicits relatively high degree of local and systemic adverse reactions probably mediated by variable amounts of undefined bacterial products, making standardization difficult; 2) the immunization schedule requires administration of six doses within an eighteen-month period, followed by annual boosters for those at risk; and 3) there is no defined vaccine-induced protective level of serum PA to evaluate new lots of vaccines.

Development of a well characterized, standardized, effective and safe vaccine that would require fewer doses to confer immunity to both inhalational and cutaneous anthrax is needed (9, 30). It has been suggested that a vaccine composed of modified purified recombinant PA would be effective, safer, allow precise standardization, and probably would require fewer injections (27). Such a PA can be designed to be biologically inactive, more stable, and still maintained high immunogenicity.

In the examples herein, we describe the development of a production and purification process for recombinant PA from the non-sporogenic avirulent *B. anthracis* BH445 ($pXO1^-$, $pXO2^-$) strain. Following an 18-hour fermentation and three purification steps, large quantities of protective antigen suitable for vaccine production were obtained. The purified PA was tested in mice and was able to elicit neutralizing antibodies.

BRIEF DESCRIPTION OF THE INVENTION

This invention relates to improved methods of preparing *Bacillus anthracis* protective antigen (PA).

The invention also relates to PA and/or compositions thereof, which are useful for inducing or eliciting an immunogenic response in mammals, including responses which provide protection against, or reduce the severity of, infections caused by *B. anthracis*. In particular, the invention relates to methods of using PA, and/or compositions thereof, to induce or elicit serum antibodies which have neutralizing activity against *B. anthracis* toxin. PA and/or compositions thereof are useful as vaccines to induce serum antibodies which are useful to prevent, treat or reduce the severity of infections caused by *B. anthracis*, such as inhalation anthrax, cutaneous anthrax and/or gastrointestinal anthrax.

The invention also relates to nucleic acids encoding PA of *B. anthracis*, and compositions thereof, which produce PA in sufficient amounts to be useful as pharmaceutical compositions or vaccines to induce serum antibodies for preventing and/or treating illnesses caused by *B. anthracis*. The invention also relates to suitable expression systems, viral particles, vectors, vector systems, and transformed host cells containing those nucleic acids.

The invention also relates to antibodies which immunoreact with the PA of *B. anthracis*, and/or compositions thereof. Such antibodies may be isolated, or may be provided in the form of serum containing these antibodies.

The invention also relates to pharmaceutical compositions and/or vaccines comprising at least one of the PAs, nucleic acids, viral particles, vectors, vector systems, transformed host cells or antibodies of the invention.

The invention also relates to methods for the prevention or treatment of *B. anthracis* infection in a mammal, by administration of pharmaceutical or vaccine compositions of the invention.

The invention also provides kits comprising one or more of the agents of the invention which are useful for vaccinating mammals for the treatment or prevention of *B. anthracis* infection.

SEQUENCE LISTING

SEQ ID NOS: 1 and 2 show an exemplary full-length PA nucleic acid and protein sequence, respectively. The signal sequence of PA is amino acids 1-29, and the mature PA protein is amino acids 30-764.

SEQ ID NO: 3 is a mature wild-type PA protein sequence.

SEQ ID NO: 4 is a PA-SNKE-ΔFF-E308D mutant protein sequence.

SEQ ID NO: 5 is a PA-N657A mutant protein sequence.

SEQ ID NO: 6 is a K397D D425K mutant PA protein sequence.

SEQ ID NO: 7 is a PA-L1 protein sequence, with a MMP cleavage site.

SEQ ID NO: 8 is a PA-L2 protein sequence, which is cleavable with MMP.

SEQ ID NO: 9 is a PrAg-U1 protein sequence, which is cleavable by uPA/tPA.

SEQ ID NO: 10 is a PrAg-U2 protein sequence, which is cleavable by uPA.

SEQ ID NO: 11 is a PrAg-U3 protein sequence, which is cleavable by uPA.

SEQ ID NO: 12 is a PrAg-U4 protein sequence, which is cleavable by tPA.

SEQ ID NO: 13 shows amino acids 175-764 of wild-type PA.

SEQ ID NO: 14 shows the amino acid RKKR which is replaced with SEQ ID NO: 15 in some PA mutants.

SEQ ID NO: 15 shows the amino acid SNKE replaces the native RKKR sequence in some PA mutants.

DETAILED DESCRIPTION OF THE INVENTION

It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only, and are not restrictive of the invention, as claimed. The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate an embodiment of the invention and, together with the description, serve to explain the principles of the invention.

The invention relates to methods of producing and recovering PA from a cell or organism, particularly a recombinant cell or microorganism. Exemplified herein is the production and purification of modified PA from a non-sporgenic strain of *Bacillus anthracis*. As discussed further herein, greater quantities of PA are obtainable from these cells or microorganisms than were obtainable by previously described methods.

The invention also relates to PA, and/or compositions thereof, which are useful for eliciting an immunogenic response in mammals, in particular humans, including responses which provide protection against, or reduce the severity of, infections caused by *B. anthracis*. The invention also relates to methods of using such PA, and/or compositions thereof, to induce serum antibodies against PA. PA, and/or compositions thereof, are useful as vaccines to induce serum antibodies which are useful to prevent, treat or reduce the severity of infections caused by *B. anthracis*, such as inhalation anthrax and/or cutaneous anthrax. The PAs of this invention are expected to induce a strong protective IgG antibody response in mammals, including humans.

The invention also relates to nucleic acids encoding PA of this invention. Nucleic acids encoding PA, and compositions thereof, are also useful as pharmaceutical compositions or vaccines to induce serum antibodies which are useful to prevent and/or treat illnesses caused by *B. anthracis*.

The invention also relates to antibodies which immunoreact with the PA of *B. anthracis* that are induced by PAs of the invention, and/or compositions thereof. Such antibodies may be isolated, or may be provided in the form of serum containing these antibodies.

The invention also relates to a method for the prevention or treatment of *B. anthracis* infection in a mammal, by administration of compositions containing one or more of a PA of the invention, nucleic acids encoding a PA if the invention, antibodies and/or serum containing antibodies of the invention.

The invention also provides kits for vaccinating mammals for the treatment or prevention of *B. anthracis* infection in a mammal comprising one or more of the agents of the invention.

The present invention also encompasses methods of using mixtures of one or more of the PA, nucleic acids, and/or antibodies of the invention, either in a single composition or in multiple compositions containing other immunogens, to form multivalent vaccine for broad coverage against either *B. anthracis* itself or a combination of *B. anthracis* and one or more other pathogens, which may also be administered concurrently with other vaccines, such as the DTP vaccine.

Pharmaceutical compositions of this invention are capable, upon injection into a human, of inducing serum antibodies against *B. anthracis*. The induced anti-PA antibodies have anthrax toxin neutralizing activity which are preferably at least comparable to those induced by the currently licensed anthrax vaccine.

The vaccines of this invention are intended for active immunization for prevention of *B. anthracis* infection, and for preparation of immune antibodies. The vaccines of this invention are designed to confer specific immunity against infection with *B. anthracis*, and to induce antibodies specific

to *B. anthracis* PA. The *B. anthracis* vaccine is composed of non-toxic bacterial components, suitable for infants, children of all ages, and adults.

The methods of using the agents of this invention, and/or compositions thereof will be useful in increasing resistance to, preventing, ameliorating, and/or treating *B. anthracis* infection in humans.

This invention also provides compositions, including but not limited to, mammalian serum, plasma, and immunoglobulin fractions, which contain antibodies which are immunoreactive with *B. anthracis* PA. These antibodies and antibody compositions may be useful to prevent, treat, and/or ameliorate infection and disease caused by the microorganism. The invention also provides such antibodies in isolated form.

High titer anti-PA sera, or antibodies isolated therefrom, may be used for therapeutic treatment for patients with *B. anthracis* infection. Antibodies elicited by the agents of this invention may be used for the treatment of established *B. anthracis* infections, and may also be useful in providing passive protection to an individual exposed to *B. anthracis*.

The present invention also provides kits comprising vaccines for the prevention and/or treatment of *B. anthracis*, containing the one or more of the PAs, nucleic acids, viral particles, vectors, vector systems, or transformed host cells or antibodies of the invention and/or compositions thereof. The PAs, nucleic acids viral particles vectors, host cells and/or antibodies of the present invention may be isolated and purified by methods known in the art. Preferably, the PA of the invention is purified by one of the methods exemplified herein.

The vaccines of the invention are intended to be included in the immunization schedule of individuals at risk for *B. anthracis* infection. They are also planned to be used for intervention in the event of the use of *B. anthracis* in bioterrorism or biowarfare. For example, it is anticipated that the vaccines of the invention may be provided to the entire U.S. population. Additionally, they may be used as component(s) of a multivalent vaccine for *B. anthracis* and/or other pathogens.

Definitions

As used herein, unless otherwise specifically noted, "PA" refers to all forms of PA which are useful in the compositions and/or methods of the invention, including unmodified native or recombinant *B. anthracis* protective antigen (PA), or a modified form (variant) or fragment thereof, for use in vaccines. Variants and fragments of PA must be able to produce an immune response in a mammal to whom they are administered. The immune response is suitably protective against infection by *Bacillus anthracis* although the protective effect may be seen only after repeated applications, as would be determinable by methods known in the art. Modified PA variants comprise peptides and proteins which resemble PA in their ability to induce or elicit antibodies which bind to native PA, but have different amino acid sequence. For example, variants may be 60% homologous to PA protein, suitably 80% homologous and more particularly at least 90% homologous. Fragments are suitably peptides which contain at least one antigenic determinant of PA.

A modified (variant) PA of the invention includes any substituted analog or chemical derivative of PA, so long as the modified (variant) PA is capable of inducing or eliciting the production of antibodies capable of binding native (or naturally-occurring) PA. Preferably, the antibodies are neutralizing antibodies. PA can be subject to various changes that provide for certain advantages in its use. For example, PA with changes which increase in vitro and/or in vivo stability of PA, while still retaining the desired immunogenic activity, are preferred. In the modified PA used in the examples herein (SEQ ID NO: 4)two regions were altered, i.e., the furin cleavage site region ($RKKR^{167}$ to $SNKE^{167}$), and the chymotrypsin and thermolysin cleavage site region (two Phe at positions 313-314 were deleted and Glu acid at position 308 was substituted with Asp), resulting in a more stable PA. As used herein, the terms "immunoreact" and "immunoreactivity" refer to specific binding between an antigen or antigenic determinant-containing molecule and a molecule having an antibody combining site, such as a whole antibody molecule or a portion thereof.

As used herein, the term "antibody" refers to immunoglobulin molecules and immunologically active portions of immunoglobulin molecules. Exemplary antibody molecules are intact immunoglobulin molecules, substantially intact immunoglobulin molecules and portions of an immunoglobulin molecule, including those portions known in the art as Fab, Fab', $F(ab')_2$ and F(v), as well as chimeric antibody molecules.

As used herein, the term "transduction" generally refers to the transfer of genetic material into the host via infection, e.g., in this case by the lentiviral vector. The term "transfection" generally refers to the transfer of isolated genetic material into cells via the use of specific transfection agents (e.g., calcium phosphate, DEAE Dextran, lipid formulations, gold particles, and other microparticles) that cross the cytoplasmic membrane and deliver some of the genetic material into the cell nucleus.

Monomers, Polymers and Polymeric Carriers

The present invention encompasses monomers of PA, as well as homogeneous or heterogeneous polymers of PA (e.g., concatenated, cross-linked and/or fused identical polypeptide units or concatenated, cross-linked and/or fused diverse peptide units), and mixtures of the polypeptides, polymers, and/or conjugates thereof. The present invention also encompasses PA bound to a non-toxic, preferably non-host, protein carrier to form a conjugate.

Linkers useful in the invention may, for example, be simply peptide bonds, or may comprise amino acids, including amino acids capable of forming disulfide bonds, but may also comprise other molecules such as, for example, polysaccharides or fragments thereof.

The linkers for use with this invention may be chosen so as to contribute their own immunogenic effect which may be either the same, or different, than that elicited by the consensus sequences of the invention. For example, such linkers may be bacterial antigens which also elicit the production of antibodies to infectious bacteria. In such instances, for example, the linker may be a protein or protein fragment of an infectious bacteria.

Carriers are chosen to increase the immunogenicity of the PA and/or to raise antibodies against the carrier which are medically beneficial. Carriers that fulfill these criteria are well known in the art. A polymeric carrier can be a natural or a synthetic material containing one or more functional groups, for example primary and/or secondary amino groups, azido groups, or carboxyl groups. Carriers can be water soluble or insoluble.

Methods for Attaching PA to a Protein Carrier.

PA of the invention may be covalently attached to other proteins, with or without a linker, by methods known in the art, such as via their side chains or via peptide bonds in the primary chain. Cysteine molecules may provide a convenient attachment point through which to chemically conjugate other proteins or non-protein moieties to PA.

Dosage for Vaccination

The pharmaceutical compositions of this invention contain a pharmaceutically and/or therapeutically effective amount of at least one PA, nucleic acid, vector, viral particle, host cell immunogen or antibody of the invention. The effective amount of immunogen per unit dose is an amount sufficient to induce an immune response which is sufficient to prevent, treat or protect against the adverse effects of infection with *B. anthracis*. The effective amount of immunogen per unit dose depends, among other things, on the species of mammal inoculated, the body weight of the mammal and the chosen inoculation regimen, as is well known in the art.

In such circumstances, inocula for a human or similarly sized mammal typically contain PA concentrations of 0.5 μg to 1 mg per mammal per inoculation dose. Initial tests of the PA vaccine in humans will use approximately 10 μg or 20 μg per dose. Preferably, the route of inoculation of the peptide will be subcutaneous or intramuscular. The dose is administered at least once.

To monitor the antibody response of individuals administered the compositions of the invention, antibody levels may be determined. In most instances it will be sufficient to assess the antibody titer in serum or plasma obtained from such an individual. Decisions as to whether to administer booster inoculations or to change the amount of the composition administered to the individual may be at least partially based on the level.

The level may be based on either an immunobinding assay which measures the concentration of antibodies in the serum which bind to a specific antigen, i.e. PA. The ability to neutralize in vitro and in vivo biological effects of the *B. anthracis* toxins may also be assessed to determine the effectiveness of the treatment.

The term "unit dose" as it pertains to the inocula refers to physically discrete units suitable as unitary dosages for mammals, each unit containing a predetermined quantity of active material calculated to produce the desired immunogenic effect in association with the required diluent.

Inocula are typically prepared in physiologically and/or pharmaceutically tolerable (acceptable) carrier, and are preferably prepared as solutions in physiologically and/or pharmaceutically acceptable diluents such as water, saline, phosphate-buffered saline, or the like, to form an aqueous pharmaceutical composition. Adjuvants, such as aluminum hydroxide, may also be included in the compositions.

Depending on the intended mode of administration, the compounds of the present invention can be in various pharmaceutical compositions. The compositions will include, as noted above, an effective amount of the selected immunogen and/or antibody of the invention in combination with a pharmaceutically acceptable carrier and, in addition, may include other medicinal agents, pharmaceutical agents, carriers, adjuvants, diluents, etc. By "pharmaceutically acceptable" is meant a material that is not biologically or otherwise undesirable, i.e., the material may be administered to an individual along with the immunogen and/or antibody or other composition without causing any undesirable biological effects or interacting in a deleterious manner with any of the other components of the pharmaceutical composition in which it is contained.

The route of inoculation may be intramuscular, subcutaneous or the like, which results in eliciting antibodies protective against *B. anthracis*. In order to increase the antibody level, a second or booster dose may be administered approximately 4 to 6 weeks after the initial injection. Subsequent doses may be administered as indicated herein, or as desired by the practitioner.

Parenteral administration, if used, is generally characterized by injection. Injectables can be prepared in conventional forms, either as liquid solutions or suspensions, solid forms suitable for solution or suspension in liquid prior to injection, or as emulsions. A more recently revised approach for parenteral administration involves use of a slow release or sustained release system, such that a constant level of dosage is maintained. See, e.g., U.S. Pat. No. 3,710,795, which is incorporated by reference herein.

Antibodies

An antibody of the present invention in one embodiment is characterized as comprising antibody molecules that immunoreact with *B. anthracis* PA.

An antibody of the present invention is typically produced by immunizing a mammal with an immunogen or vaccine containing an *B. anthracis* PA to induce, in the mammal, antibody molecules having immunospecificity for the immunizing PA. Antibody molecules having immunospecificity for the protein carrier will also be produced. The antibody molecules may be collected from the mammal and, optionally, isolated and purified by methods known in the art.

Human or humanized monoclonal antibodies are preferred, including those made by phage display technology, by hybridomas, or by mice with human immune systems. The antibody molecules of the present invention may be polyclonal or monoclonal. Monoclonal antibodies may be produced by methods known in the art. Portions of immunoglobulin molecules, such as Fabs, may also be produced by methods known in the art.

The antibody of the present invention may be contained in blood plasma, serum, hybridoma supernatants and the like. Alternatively, the antibodies of the present invention are isolated to the extent desired by well known techniques such as, for example, ion exchange chromatography, sizing chromatography, or affinity chromatography. The antibodies may be purified so as to obtain specific classes or subclasses of antibody such as IgM, IgG, IgA, IgG_1, IgG_2, IgG_3, IgG_4 and the like. Antibodies of the IgG class are preferred for purposes of passive protection. The antibodies of the present invention have a number of diagnostic and therapeutic uses. The antibodies can be used as an in vitro diagnostic agents to test for the presence of *B. anthracis* in biological samples or in meat and meat products, in standard immunoassay protocols. Such assays include, but are not limited to, agglutination assays, radioimmunoassays, enzyme-linked immunosorbent assays, fluorescence assays, Western blots and the like. In one such assay, for example, the biological sample is contacted first with antibodies of the present invention which bind to *B. anthracis* PA, and then with a labeled second antibody to detect the presence of *B. anthracis* to which the first antibodies have bound.

Such assays may be, for example, of direct format (where the labeled first antibody is reactive with the antigen), an indirect format (where a labeled second antibody is reactive with the first antibody), a competitive format (such as the addition of a labeled antigen), or a sandwich format (where both labeled and unlabelled antibody are utilized), as well as other formats described in the art. The antibodies of the present invention are also useful in prevention and treatment of infections and diseases caused by *B. anthracis*.

In providing the antibodies of the present invention to a recipient mammal, preferably a human, the dosage of administered antibodies will vary depending upon such factors as the mammal's age, weight, height, sex, general medical condition, previous medical history and the like.

In general, it is desirable to provide the recipient with a dosage of antibodies which is in the range of from about 1

mg/kg to about 10 mg/kg body weight of the mammal, although a lower or higher dose may be administered. The antibodies of the present invention are intended to be provided to the recipient subject in an amount sufficient to prevent, or lessen or attenuate the severity, extent or duration of the infection by *B. anthracis*. When proteins of other organisms are used as carriers, antibodies which immunoreact with those proteins are intended to be provided to the recipient subject in an amount sufficient to prevent, lessen or attenuate the severity, extent or duration of an infection by the organisms producing those proteins.

The administration of the agents of the invention may be for either "prophylactic" or "therapeutic" purpose. When provided prophylactically, the agents are provided in advance of any symptom. The prophylactic administration of the agent serves to prevent or ameliorate any subsequent infection. When provided therapeutically, the agent is provided at (or shortly after) the onset of a symptom of infection. The agent of the present invention may, thus, be provided prior to the anticipated exposure to *B. anthracis*, so as to attenuate the anticipated severity, duration or extent of an infection and disease symptoms, after exposure or suspected exposure to these bacteria, or after the actual initiation of an infection.

For all therapeutic, prophylactic and diagnostic uses, one or more of the PAs or other agents of this invention, as well as antibodies and other necessary reagents and appropriate devices and accessories, may be provided in kit form so as to be readily available and easily used.

Nucleic Acids, Vectors and Hosts

The invention also relates to isolated and purified nucleic acid molecules which code for the PAs of the invention. The encoded PAs may be monomers, polymers or linked to other peptide sequences (e.g., they may be fusion proteins).

Nucleic acids encoding the PAs of the invention can be introduced into a vector such as a plasmid, cosmid, phage, virus, viral particle or mini-chromosome and inserted into a host cell or organism by methods well known in the art. The vectors which can be utilized to clone and/or express these nucleic acids are the vectors which are capable of replicating and/or expressing the nucleic acids in the host cell in which the nucleic acids are desired to be replicated and/or expressed. See, e.g., F. Ausubel et al., Current Protocols in Molecular Biology, Greene Publishing Associates and Wiley-Interscience (1992) and Sambrook et al. (1989) for examples of appropriate vectors for various types of host cells. Vectors and compositions for enabling production of the peptides in vivo, i.e., in the individual to be treated or immunized, are also within the scope of this invention. Strong promoters compatible with the host into which the gene is inserted may be used. These promoters may be inducible. The host cells containing these nucleic acids can be used to express large amounts of the protein useful in pharmaceuticals, diagnostic reagents, vaccines and therapeutics. Vectors include retroviral vectors and also include direct injection of DNA into muscle cells or other receptive cells, resulting in the efficient expression of the peptide, using the technology described, for example, in Wolff et al., Science 247:1465-1468 (1990), Wolff et al., Human Molecular Genetics 1(6):363-369 (1992) and Ulmer et al., Science 259:1745-1749 (1993). See also, for example, WO 96/36366 and WO 98/34640.

In general, vectors containing nucleic acids encoding PA can be utilized in any cell, either eukaryotic or prokaryotic, including mammalian cells (e.g., human (e.g., HeLa), monkey (e.g., COS), rabbit (e.g., rabbit reticulocytes), rat, hamster (e.g., CHO and baby hamster kidney cells) or mouse cells (e.g., L cells), plant cells, yeast cells, insect cells or bacterial cells (e.g., *E. coli*). However, bacterial vectors and host cells are preferred in the present invention.

There are numerous *E. coli* expression vectors known to one of ordinary skill in the art useful for the expression of PA. Other microbial hosts suitable for use include bacilli, such as *B. subtilus*, and other enterobacteriaceae, such as *Salmonella, Serratia*, and various *Pseudomonas* species. In these prokaryotic hosts one can also make expression vectors, which will typically contain expression control sequences compatible with the host cell (e.g., an origin of replication). In addition, any number of a variety of well-known promoters will be present, such as the lactose promoter system, a tryptophan (Trp) promoter system, a beta-lactamase promoter system, or a promoter system from phage lambda. The promoters will typically control expression, optionally with an operator sequence, and have ribosome binding site sequences for example, for initiating and completing transcription and translation. If necessary an amino terminal methionine can be provided by insertion of a Met codon 5' and in-frame with the antigen. Also, if desired, the carboxy-terminal or other region of the antigen can be removed using standard oligonucleotide mutagenesis procedures.

The nucleotide (DNA) sequences can be expressed in hosts after the sequences have been operably linked to, i.e., positioned to ensure the functioning of, an expression control sequence. These expression vectors are typically replicable in the host organisms either as episomes or as an integral part of the host chromosomal DNA. Commonly, expression vectors can contain selection markers, e.g., tetracycline resistance or hygromycin resistance, to permit detection and/or selection of those cells transformed with the desired DNA sequences (see, e.g., U.S. Pat. No. 4,704,362).

Host bacterial cells may be chosen that are mutated to be reduced in or free of proteases, so that the proteins produced are not degraded. For *bacillus* expression systems in which the proteins are secreted into the culture medium, strains are available that are deficient in secreted proteases.

Polynucleotides encoding a variant polypeptide may include sequences that facilitate transcription (expression sequences) and translation of the coding sequences such that the encoded polypeptide product is produced. Construction of such polynucleotides is well known in the art. For example, such polynucleotides can include a promoter, a transcription termination site (polyadenylation site in eukaryotic expression hosts), a ribosome binding site, and, optionally, an enhancer for use in eukaryotic expression hosts, and, optionally, sequences necessary for replication of a vector.

Fermentation and Purification Procedures

This invention relates to improved methods of preparing *B. anthracis* PA for use in vaccines. Procedures are exemplified herein for purifying modified PA from is a protease-deficient nonsporogenic avirulent strain of *B. anthracis*. However, it is expected that these procedures will be useful for growing and purifying PA, including natural or recombinant PA, as well as various modified or truncated forms of PA, from other microorganisms, particularly *Bacillus. Bacillus* strains and/or expression systems which are expected to be suitable include, for example, the *B. anthracis* strain described in U.S. Pat. No. 5,840,312 (Nov. 24, 1998) and the *B. subtilis* strain and PA expression system described in U.S. Pat. No. 6,267,966 (Jul. 31, 2001).

In the method of the invention, the culture is preferably maintained at about pH 7 to about pH 8, most preferably about pH 7.5, substantially throughout the fermentation process. It has also been found to be advantageous to add EDTA before separating the culture supernatant from the cells, pref-

erably at or near the end of fermentation, since if it is added during the fermentation stage, it may interfere somewhat with the growth of the cells.

The purification procedure of the invention is preferably essentially a three-step procedure, including (1) hydrophobic interaction chromatography, (2) ion exchange chromatography and (3) gel filtration. While ion exchange chromatography may precede hydrophobic interaction chromatography in the purification process, and still permit obtaining a good yield of PA, it is a less efficient process. Therefore, in view of this, it is preferred that hydrophobic interaction chromatography precede ion exchange chromatography in the purification process. Alternatively, this three step procedure need not be used and an alternative purification scheme may be used.

In addition, the resins used in the exemplified the purification procedure can be substituted. For example, in the hydrophobic interaction chromatography step, phenyl sepharose (Pharmacia) is used as the resin in the example, but any other hydrophobic resin can be used. Likewise, in the ion exchange chromatography step, Q sepharose (Pharmacia) is used as the resin in the example, but any other anion exchanger can be used. Likewise, for the gel filtration step, Superdex (Pharmacia) is the residue used in the example, but it can be replaced by other gel filtration resins. Furthermore, with respect to the fermentation conditions, similar compounds can replace the tryptone and the yeast extract that are obtained from Difco.

The expression and the stability of two recombinant PA variants, PA-SNKE-ΔFF-E 308D (SEQ ID NO: 4) and PA-N657A (SEQ ID NO: 5),were studied. However, the methods of the invention are also expected to be useful for producing and recovering native PA; PA wherein the receptor-binding domain has been altered; PA which cannot be cleaved at the chymotrypsin cleavage site; PA which cannot be cleaved at the furin cleavage site; other PA which cannot be cleaved at either the chymotrypsin or the furin cleavage site in addition to the one exemplified herein (see, e.g., those described in (22)); PA fragments (e.g., a PA fragment having aa 175-764 (36), SEQ ID NO: 13); PA mutants having a strong dominant-negative effect (e.g., PA double mutants K397D and D425K, SEQ ID NO: 6) (37), and PA mutants with substitutions in domain 2 (37)).

In addition, the methods of the invention are also expected to be useful for producing and recovering PA in which the chymotrypsin site, FF, is replaced by a furin site. This may be a suicide protein, getting easily cleaved by furin after binding to receptor. Cleavage at that site inactivates PA.

The methods of the invention are also expected to be useful for producing and recovering PA with a protease cleavage site (thrombin, Factor IV, etc.) at approximately residue 605. PA made in large amounts in the expression system could be cleaved to produce a soluble domain 4, which would compete with PA for receptor, and could be a therapeutic agent.

The methods of the invention are also expected to be useful for producing and recovering PA with matrix metalloprotease or plasminogen activator sites replacing the furin site (38, 39, SEQ ID NO: 7-12).

The methods of the invention are also expected to be useful for producing and recovering other proteins, such as LF. See, e.g., (21), wherein expression system is the same, except the structural gene for PA is replaced by the LF gene. This can be generalized to include LF mutants altered in the catalytic site residues: HEFGH, 686-690. The system may also have utility with EF.

The following examples are exemplary of the present processes and incorporate suitable process parameters for use herein. These parameters may be varied, however, and the following should not be deemed limiting.

EXAMPLE 1

In this example, the expression and the stability of two recombinant PA variants, PA-SNKE-ΔFF-E308D (SEQ ID NO: 4)and PA-N657A (SEQ ID NO: 5), were studied. These proteins were expressed in the non-sporogenic avirulent strain BH445. Initial results indicated that PA-SNKE-ΔFF-E308D (SEQ ID NO: 4),which lacks two proteolysis-sensitive sites, is more stable than PA-N657A (SEQ ID NO: 5). Process development was conducted to establish an efficient production and purification process for PA-SNKE-ΔFF-E308D (SEQ ID NO: 4). Various parameters such as pH, media composition, growth strategy, and protease inhibitors composition were analyzed. The production process chosen was based on batch growth of *B. anthracis* using tryptone and yeast extract as the only sources of carbon, pH control at 7.5, and antifoam 289. Optimal harvest time was found to be 14-18 hours after inoculation, and EDTA (5 mM) was added upon harvesting for proteolysis control. In one of the processes described herein, recovery of the PA was performed by expanded bed adsorption (EBA) on a hydrophobic interaction resin, eliminating the need for centrifugation, microfiltration, and diafiltration. The EBA step was followed by ion exchange and gel filtration. PA yields before and after purification were 130 mg/L and 90 mg/L, respectively.

Materials and Methods

Strains and Plasmids

The non-sporogenic, protease deficient, avirulent strain *B. anthracis* BH445 ($pXO1^-$, $pXO2^-$, cm^r) was used (17). The *Bacillus-E. coli* shuttle vector pYS5 (amp^r, kan^r)(26) was used to clone two recombinant forms of the protective antigen: N657A and SNKE-ΔFF-E308D (SEQ ID NO: 4) (28). In the N657A mutant (SEQ ID NO: 5), the receptor-binding domain of PA was altered by substitution of Asn with Ala at position 657 (domain 4). In the SNKE-ΔFF-E308D mutant (SEQ ID NO: 4) two regions were altered, the furin site ($RKKR^{167}$ to $SNKE^{167}$) and the chymotrypsin site (two Phe at positions 313-314 were deleted and Glu acid at position 308 was substituted with Asp). Both PA constructs contain the DNA sequence encoding the signal peptide of PA.

Culture and Expression Conditions

Modified FA medium (21) containing (per liter) 35 g tryptone (Difco Laboratories, Detroit, Mich.), 5 g yeast extract (Difco Laboratories), and 100 mL of 10× salts was used in all experiments. The 10× salt solution (per liter) consisted of 60 g Na 2 $HPO_4.7H_2O$, 10 g KH_2PO_4, 55 g NaCl, 0.4 g L-tryptophan, 0.4 g L-methionine, 0.05 g thiamine, and 0.25 g uracil. It was filter-sterilized and added to the fermentor after cooling. The pH of the medium was adjusted to 7.5; 100 μg/mL kanamycin and 20 μg/mL chloramphenicol were added. Fermentation experiments were performed by inoculating a 12-14 hour-old starter culture grown from a frozen stock. The medium in the fermentor was supplemented with 0.2 mL/L of antifoam 289 (Sigma, St. Louis, Mo.). Three- to ten-liter fermentations were done using B. Braun Biostat MD DCU (Melsungen, Germany), controlling dissolved oxygen (DO) at 30% saturation, temperature at 37° C., and pH at 7.5 with HCl and NH_4OH. At harvest time, 5 mM EDTA and 10 μg/mL PMSF (phenylmethyl sulfonyl fluoride) (in one of the experiments described herein) were added to the culture. Shake flask experiments (100 mL) utilizing modified FA medium were supplemented with glucose, lactose, glycerol, and casitone at a concentration of 10 g/L.

Analytical Methods

Optical density (OD) was measured at 600 nm. Protease analysis was done on supernatant samples collected during growth and stored frozen at −20° C. EDTA was added to supernatant samples used for SDS-PAGE and radial immunodiffusion to a final concentration of 10 mM.

Extracellular protease activity was detected using the EnzChek green fluorescence assay kit (Molecular Probes Eugene, Oreg.). Fluorescence was measured with a LS508 luminescence spectrophotometer (Perkin-Elmer Boston, Mass.). This assay was conducted at pH of 7.5 or 6.0 depending on the experiment. Proteolytic activity is reported as fluorescence change per unit sample.

Protein was determined using BCA assay (Pierce Rockford, Ill.). PA expression was quantified by SDS-PAGE (Invitrogen/Novex, Carlsbad, Calif.) gel analysis and by the Mancini immunodiffusion assay (19) using agarose plates containing polyclonal PA antibody. Pure PA was used as the standard, both polyclonal PA antibodies and pure PA were supplied by S. Leppla

Purification

a. Packed Bed Hydrophobic Interaction Chromatography

The cell suspension containing 5 mM EDTA was centrifuged and the supernatant passed through a 0.2 μm hollow fiber filter (AGT, Needham, Mass.). The filtered broth was then concentrated 20× using a 10K membrane in a Pellicon-2 (Millipore, Bedford, Mass.). 200 g $(NH_4)_2SO_4$ per liter (1.5 M) were added to the concentrated supernatant. The small amount of precipitate produced after addition of $(NH_4)_2SO_4$ was eliminated with centrifugation and filtration. Phenyl Sepharose Fast Flow (Amersham Pharmacia Biotech) was equilibrated with buffer containing 1.5 M $(NH_4)_2SO_4$/10 mM HEPES/5 mM EDTA pH=7.0 (equilibration buffer) at a flow rate of 15 cm/h. After sample loading, the column was washed with 10 column volumes (CV) of equilibration buffer and PA was eluted with a 30 CV linear gradient from 1.5 M to 0 M $(NH_4)_2SO_4$ in 10 mM HEPES/5 mM EDTA; pH=7.0. Fractions were analyzed by SDS-PAGE and the PA-containing samples were pooled for further purification.

b. Expanded Bed Hydrophobic Interaction Chromatography

The cell suspension containing 5 mM EDTA was diluted 1:1 with buffer containing 3.0 M $(NH_4)_2SO_4$/20 mM HEPES/5 mM EDTA and 0.005% Pluronic F-68 (Life Technologies, Inc. Gaithersburg, Md.). STREAMLINE™ Phenyl adsorbent. (Amersham Pharmacia Biotech) was expanded in a streamline column in equilibration buffer. The diluted cell suspension was loaded upward at 300 cm/h. The column was washed in expanded mode (2) with 10 CV of equilibration buffer containing 0.005% pluronic F-68. Elution was performed in packed bed mode with 8 CV of elution buffer at 100 cm/h. The eluent was analyzed by SDS-PAGE and radial immunodifussion.

c. Anion Exchange Chromatography

Fractions from HIC were dialyzed against 20 mM Tris pH=8.9 and loaded on a Q Sepharose Fast Flow (Amersham Pharmacia Biotech) column equilibrated with 20 mM Tris pH=8.9 at 15 cm/h. The protein was eluted using a 20 CV linear gradient from 0 to 0.5 M NaCl in the same buffer. PA containing fractions were concentrated and dialyzed against PBS.

d. Gel Filtration

The pooled PA was further purified using a Superdex 75 column (Amersham Pharmacia Biotech) in PBS/5 mM EDTA pH=7.4 at 12 cm/h.

Results and Discussion

a. Expression of Two Recombinant PA: PA-N657A and PA-SNKE-AFF-E308D

The expression of two recombinant versions of PA and the extracellular proteolytic activity of the culture were analyzed (FIG. **1**). Production of PA-SNKE-ΔFF-E308D (SEQ ID NO: 4)the protein lacking the furin and chymotrypsin cleavage sites, was nearly 60% higher than that of PA-N657A (SEQ ID NO: 5),the protein containing a mutation in the receptor-binding domain (FIG. **1***a*). The extracellular proteolytic activity (fluorescence/OD) of both cultures was similar. SDS-PAGE analysis of partially purified PA recovered from these cultures shows higher concentration of smaller fragments in the sample from PA-N657A (SEQ ID NO: 5)compared to the sample from PA-SNKE-ΔFF-E308D (FIG. **1***b*; SEQ ID NO: 4). Western blot analysis with polyclonal PA antibody confirmed that the smaller fragments were reactive against PA (data not shown). As indicated in FIG. **1***a*, the proteolytic activity was similar in both strains. Therefore, it was apparent that PA-SNKE-ΔFF-E308D (SEQ ID NO: 4) is a better candidate, due to its stability, and it was selected for further studies.

b. pH Effect

Based on previous information (5, 21), initial production studies with PA-SNKE-ΔFF-E308D (SEQ ID NO: 4) were done by controlling pH with NH_4OH only, which resulted in pH 8.7 at the end of the fermentation. When pH was controlled at 7.4 during the entire fermentation, the PA production was 30 mg per g cell and the proteolytic activity per OD unit was 8, compared to values of 20 mg PA per g cells and proteolytic activity per OD of 30 when the pH control was done only by NH_4OH. When the process was performed at a lower pH, both PA production and protease activity were lower. At pH 6.1 production declined nearly six times and protease activity two times compared to what was found at pH 7.4. Possibly, intracellular expression is lower or secretion is inhibited at low pH. From the above information it is obvious that pH significantly affects the proteolytic activity and the PA expression. Controlling pH throughout the fermentation process resulted in a 30% increase in PA yield, compared to previously reported strategies.

c. Effect of Various Carbon Sources and Protease Inhibitors

Attempts to increase PA expression by supplementing the basic growth medium with different carbon sources is summarized in Table 1.

TABLE 1

Effect of various carbon sources on PA production.

	PA production	
Medium	mg PA/g cell	mg PA/L culture
Basic medium	31.3	129.5
Glycerol + basic medium	23.7	117.3
Glucose + basic medium	25.3	113.3
Lactose + basic medium	33.9	116.0
Casitone + basic medium	28.3	135.1

Neither the volumetric production nor the production per gram cells could be enhanced with the addition of various carbon sources. The effect of PMSF and EDTA on extracellular proteolysis was also examined. As shown in FIG. **2**, addition of EDTA (15 mM) significantly reduced proteolytic activity whereas the proteolytic activity of the PMSF-containing fraction (1 g/mL) was similar to that of the control.

Based on this information, EDTA was added at the end of the fermentation, before the protein was processed.

d. Growth and Production Conditions

Based on the parameters determined previously, a production process for the recombinant PA-SNKE-ΔFF-E308D (SEQ ID NO: 4)from *B. anthracis* BH445 was established. The process is based on growth in a batch fermentation controlled at pH 7.5 with NH_4OH/HCl and at 30% dissolved oxygen saturation for a period of 18 hours. A typical fermentation is seen in FIG. **3**.

In general, the final OD_{600} values fluctuated between 16 to 20. During the first five hours, growth was exponential and the pH was controlled by base addition. Later in the fermentation the pH was controlled by acid addition. Accumulation of PA occurred mostly during the stationary phase and reached a final concentration of 160 mg per liter. The results shown in FIG. **4** indicate that PA degraded if the fermentation was extended for more than 18 hours, therefore, a harvest time between 14 and 18 hours was selected.

Attempts to increase the PA production by implementing a fed-batch growth strategy were conducted. The addition of 10× tryptone/yeast extract/salts or 50% glucose/10× salts resulted in a 50% increase in cell density but not an increase in protein production (FIG. **5**). The observations that PA production was not improved by the implementation of a fed batch growth strategy or by the addition of various carbon sources such as casein, glucose, glycerol or lactose is an indication that perhaps a specific nutritional factor is missing. It is also important to mention that the specific proteolytic activity was almost five times lower when glucose was added to the tryptone/yeast extract media (FIG. **6**). This was expected since glucose is known to be a repressor of proteases in *Bacillus* (10, 25).

e. Purification

The purification protocol developed for PA (Materials and Methods) consisted of hydrophobic interaction chromatography (Phenyl Sepharose) followed by anion exchange (Q Sepharose) and gel filtration (Superdex 75). Replacing the initial capturing step with expanded bed chromatography (2) can simplify and shorten the recovery process since it eliminates the clarification steps. Therefore, the use of expanded bed adsorption (EBA) was investigated by substituting the traditional packed-bed resin (Phenyl Sepharose) with the expanded bed hydrophobic resin STREAMLINE™ Phenyl. The static binding capacity for STREAMLINE™ Phenyl was approximately 15 mg protein/mL of resin which is comparable to the capacity of Phenyl Sepharose. Optimal binding of PA to S STREAMLINE™ Phenyl adsorbent occurred at 1.5 M $(NH_4)_2SO_4$.

Preliminary experiments performed with cell-containing broth in expanded mode resulted in the formation of aggregates and eventual collapse of the bed. It was possible to stabilize the expanded column only after the addition of a detergent which probably altered some of the hydrophobic interactions but did not prevent PA from binding. Pluronic F-68 was chosen due its non-toxicity in humans. The static binding capacities of STREAMLINE™ Phenyl adsorbent were 15, 11, and 5 mg protein/mL resin with 0%, 0.005%, and 0.01% pluronic F-68, respectively. Successful operation of the HIC EBA column occurred when using a load concentration of 15 g wet cells/L, 0.8 mL resin/g wet cells, and 0.005% pluronic F-68 in the load as well as the wash buffer. Under these conditions some signs of aggregation appeared at the end of the loading phase but cell debris was eliminated in the washing phase. A 70% recovery was obtained.

PA purity after hydrophobic interaction chromatography was higher than 80%. Further purification was achieved by adding gel filtration step (FIG. **6**, Lane b). However, this material was not stable when stored at 4° C. for three months (FIG. **6**, Lane c). In contrast, pure and stable PA was obtained after hydrophobic interaction chromatography on expanded bed, followed by anion exchange and gel filtration (FIG. **6**, Lane d). Similar results to the expanded bed process were obtained when packed bed hydrophobic interaction chromatography was followed by ion exchange and gel filtration (FIG. **6**, Lane a).

Replacing the packed-bed capturing step with expanded bed adsorption proved to be more efficient since it eliminated the centrifugation and filtration steps, however, twenty times more $(NH_4)_2SO_4$ and three times more resin were required to process the same amount of culture (Table 2).

TABLE 2

Comparison of packed bed and expanded bed absorption as capturing processes for PA

Packed Bed	Expanded Bed Adsorption
1. Total processing time 15.5 h a) downstream processing: 6 h (4 unit operations) b) loading: 2 h c) column wash: 3.5 h d) elution: 4 h 2. 400 g $(NH_4)_2SO_4$ needed 3. 100 mL resin needed 4. Load/wash steps require little attention 5. 82% recovery	1. Total processing time: 8 h a) downstream processing: 1 h (1 unit operation) b) loading: 4 h c) column wash: 1.5 h d) elution: 1.5 h 2. 8000 g $(NH_4)_2SO_4$ needed 3. 300 mL resin needed 4. Load/wash steps cannot be left unattended 5. 70% recovery

Initial work with hydrophobic interaction chromatography using expanded bed ad sorption to capture PA resulted in bed collapse. This was avoided after the addition of a surfactant (pluronic F-68). These results suggest that the characteristics of the cell membrane were most likely the cause of cell aggregation. Since no polyglutamic acid capsule is present in the recombinant strain, the two hydrophobic membrane proteins forming the S-layer (4, 6) may be responsible for associating with neighboring cell membranes and the resin. After evaluating the possible interactions affecting the system, it was found that successful operation of the expanded bed was possible by carefully adjusting the cell concentration of the load, increasing the adsorbent-to-cell ratio, and choosing the appropriate detergent type and concentration. The expanded bed approach was more efficient in spite of the slightly lower yield (70% vs. 82%) and the higher amount of $(NH_4)_2SO_4$ and resin needed since it eliminated the need for centrifugation and filtration. To obtain stable and highly purified protein, anion exchange and gel filtration steps were added.

Conclusions

Once the gene encoding PA (pagA) was cloned (31) and sequenced (32), several researchers have reported on the expression of PA in hosts like *B. subtilis* (1, 13, 20, 26), *E. coli* (8, 24, 31), *Salmonella typhimurium* (3), viruses (11), and avirulant *B. anthracis* (5, 15). From these reports, the highest PA yield achieved has been in the order of 50 mg/L in *B. anthracis* (15). In this work, a scalable fermentation and purification process suitable for vaccine development which produced almost three times more product than what have been reported earlier, is presented. This was accomplished by using a biologically inactive protease-resistant PA variant in a protease-deficient nonsporogenic avirulent strain of *B. anthracis*.

EXAMPLE 2

Composition of the Vaccines

Four combinations of the recombinant (modified) protective antigen ("rPA") were made: (1) rPA in PBS ("phosphate buffered saline"), (2) rPA in formalin, (3) rPA in aluminum hydroxide and (4) rPA in formalin and aluminum hydroxide. Another formulation of succinylated rPA was prepared and tested (data not shown).

EXAMPLE 3

Immunogenicity in Mice

The four formulations described above were immunogenic in mice, and induced antibody levels comparable to those induced by the currently licensed anthrax vaccine. The induced antibodies had anthrax toxin neutralizing activity. It is planned to evaluate these formulations in humans, and to chose the best one for use as a vaccine.

The data from the mice experiments are set forth in the tables 3 to 5 below:

5-6 weeks old female general purpose mice were injected subcutaneously with 0.1 mL of the immunogens depicted in Table 3, 2 or 3 times 2 weeks apart. The mice were exsanguinated one week after the last injection and their sera assayed for IgG anti PA and anthrax toxin neutralization. Antibodies measured by Elisa were related to a standard containing 1.8 mg/ml of anti-PA monoclonal antibody.

```

We claim:

1. A method for vaccinating a human against *B. anthracis* infection, comprising administering to the human an immunizing amount of a vaccine composition comprising a modified *Bacillus anthracis* (*B. anthracis*) protective antigen, wherein the antigen comprises a *B. anthracis* protective antigen shown in SEQ ID NO: 3 modified such that the amino acid sequence $RKKR^{167}$ (SEQ ID NO: 14) has been changed to $SNKE^{167}$ (SEQ ID NO: 15), the two phenylalanines at positions 313-314 are deleted, and the glutamic acid at position 308 is substituted with aspartic acid.

2. The method of claim **1**, wherein the vaccine composition further comprises a physiologically acceptable carrier and aluminum hydroxide.

3. The method of claim **1**, wherein the vaccine composition further comprises a physiologically acceptable carrier.

4. The method of claim **3**, wherein the physiologically acceptable carrier comprises saline or phosphate-buffered saline.

5. The method of claim **1**, wherein the vaccine composition further comprises an adjuvant.

6. The method of claim **5**, wherein the adjuvant comprises aluminum hydroxide.

7. The method of claim **1**, wherein the vaccine composition further comprises formalin.

8. The method of claim **1**, wherein the vaccine composition further comprises an adjuvant and formalin.

9. The method of claim **1**, wherein the *B. anthracis* protective antigen that has been modified comprises the amino acid sequence shown in SEQ ID NO: 4.

10. The method of claim **1**, wherein the *B. anthracis* protective antigen that has been modified consists of the amino acid sequence shown in SEQ ID NO: 4.

* * * * *
